

Stage-4 Figure 1 — What does "natural organization at the same target" mean?

A: target $Y = (x_1 + x_2 + x_3)/3$

B: natural mean profile at $Y=1$

C: decomposition $m = m_{\text{nat}}(Y) + r$

$$m = m_{\text{nat}}(Y) + r$$

$$m_{\text{nat}}(Y) = vY$$

the microstate the system would naturally adopt to have this Y , under its OWN endogenous coupling

$$r = m - vY, \quad c^T r = 0$$

r changes microscopic organization WITHOUT changing the macro-target Y

$$d_{\perp} = \frac{1}{2} m^T Q_{\perp} m = \frac{1}{2} r^T \Omega_0 r$$

excess distortion beyond what Y alone requires -- the Stage-4 disruption metric
